Task Brief — Scanned Invoice Data Extraction

14 July 2026

The Task

Given a scanned invoice (image or PDF), extract the following fields into structured JSON. Treat this as the exact shape a downstream system would consume — field names matter, types matter, and a missing field should be null, not omitted.

Field	Type	Notes
invoice_number	string	Required
invoice_date	date	Required — normalize to ISO 8601 (YYYY-MM-DD)
due_date	date	Optional
vendor_name	string	Required — the issuing company
vendor_tax_id	string	Optional — GSTIN / VAT / EIN, whichever is present
buyer_name	string	Optional
line_items	array	See sub-fields below
total_amount	float	Required — the final payable total
currency	string	e.g. USD, INR — infer from symbol/context if not explicit

Each entry in **line_items** should include, at minimum:

```
{"description": "...", "quantity": 0, "unit_price": 0.00, "line_total": 0.00}
```

Alongside each extracted field, include a **confidence score** (0.0-1.0, your own definition — just be consistent and explain it in your write-up) and, if feasible, the approximate bounding box on the page where the value was found.
